

Blynk

A browser-based, privacy-first eye and posture wellness monitor

- Uses real-time, on-device AI to track eye strain and posture while you work
- Zero data ever leaves your laptop — no server, no video recorded or uploaded
- Built entirely client-side using computer vision

Motivation

Why Blynk Exists

- Students and professionals spend 6–10+ hours daily on screens
- Prolonged screen time causes reduced blink rate (dry, strained eyes) and poor posture ("tech neck")
- Existing tools (timers, reminder apps) are generic and don't verify if you actually took a break or did anything about it
- A real-time, personalized, and private way to monitor this is missing from most people's daily workflow

Problem Statement

Three critical gaps define the current landscape: no real-time personalized feedback, passive timers that don't verify recovery, and privacy-invasive data collection.

- People have no real-time, personalized feedback on eye strain or posture while working
- Most health-monitoring solutions require uploading video or data to a server, raising serious privacy concerns
- **The need:** a lightweight, private, real-time system that both measures strain and actively enforces recovery

Proposed Solution

Privacy-First Architecture

Runs entirely in-browser using on-device AI (face and posture landmark detection). No video ever leaves the device.

Real-Time Dashboard

Live gauges for blink rate and screen distance, with a calming ambient visual that reflects current strain level.

Enforced Eye-Exercise Breaks

Camera-verified 20-20-20 rule breaks — the app checks you're actually following the on-screen exercise before unlocking.

History Tracking

Local storage of daily and weekly trends to identify patterns over time.

Stretch Goals

Posture detection and a native desktop widget for always-on tracking.
